# 2 Typed Syntax

This mostly follows from Figure 10.13 with modified rules for the context. ( $\Sigma$ ;  $\Delta$ ;  $\Gamma$ , x: A becomes  $\Sigma$ ;  $\Delta$ ; ( $\Gamma$ ; x: A), replacing ', with '; '). The additional rules for the new connectives are below.

Normally, separation logic would partition the value context. In this case, we have a type context and a case store. Here, it seems we don't care about partitioning the type variable context. The case store is a bit trickier.. The typing rules for the original CBPV OSum in figure 10.13 demonstrate that the case store is not updated in the typing. This is also true for the cast calculus, PolyC, which introduced the type tag store for its operational semantics (see figure 10.11). The CBPV OSum typing show that the newcase term updates the value context, and it should also update the case store in the operational semantics of CPBV Osum. Thus for typing purposes, we only require the value contexts to be distinct.

$$\frac{\sum, \Delta, \Gamma_1 \vdash V_1 : A_1}{\sum, \Delta, \Gamma_2 \vdash V_2 : A_2} *Intro$$

$$\frac{\sum, \Delta, \Gamma_1(x : A \circ y : B) \mid \cdot \vdash N : C}{\sum, \Delta, \Gamma_1(x : A \circ y : B) \mid \cdot \vdash N : C} *Elim$$

$$\frac{\sum, \Delta, \Gamma_1(x : A \circ y : B) \mid \cdot \vdash Plet(x, y) = M \text{ in } N : C}{\sum, \Delta, \Gamma_1(\Gamma_2) \mid \cdot \vdash Plet(x, y) = M \text{ in } N : C} *Elim$$

$$\frac{\Delta \vdash A \qquad \sum, \Delta, \Gamma_1(\Gamma_2) \mid \cdot \vdash Plet(x, y) \mid \cdot \vdash M : B}{\sum, \Delta, \Gamma_1 \mid \cdot \vdash \Gamma(\alpha x : A, M) : A \twoheadrightarrow B} \twoheadrightarrow Intro$$

$$\frac{\sum, \Delta, \Gamma_1 \mid \Theta \vdash M : A \twoheadrightarrow B}{\sum, \Delta, \Gamma_1 \mid \Theta \vdash M : A \twoheadrightarrow B} \times \int, \Delta, \Gamma_2 \vdash V : A} \times Elim$$

$$\frac{\sum, \Delta, \Gamma_1 \mid \Theta \vdash M : A \twoheadrightarrow B}{\sum, \Delta, \Gamma_1 \mid \Theta \vdash M : A \twoheadrightarrow B} \times Elim$$

reconsider the rules with \_: Case\_

# 3 Type and Environment Translation

Here lies the motivation for this exercise. But to make sense of this, we need to check that the cast calculus can be faithfully translated.

$$[\![\Sigma, \Gamma \vdash \exists^v X.A]\!] = \exists X.U(CaseX *F[\![\Sigma, \Gamma, X \vdash A]\!])$$
$$[\![\![\Sigma, \Gamma \vdash \forall^v X.A]\!] = U(\forall X.CaseX *F[\![\Sigma, \Gamma, X \vdash A]\!])$$

Figure 1: Type Translation Fragment

First, consider the environment translation. For the following equations, assume  $[\![\Sigma \vdash \Gamma]\!] = \Delta'$ ;  $\Gamma'$ .

$$[\![ \Sigma \vdash \cdot ]\!] = \cdot; \cdot$$

$$\begin{split} \llbracket \Sigma \vdash \Gamma, x : A \rrbracket &= \Delta'; \; (\Gamma'; \; x : \llbracket \Sigma; \; \Gamma \vdash A \rrbracket) \\ \llbracket \Sigma \vdash \Gamma, X \rrbracket &= \Delta', X; \; (\Gamma' \, ; \; c_x : CaseX) \\ \llbracket \Sigma \vdash \Gamma, X \cong A \rrbracket &= \Delta'; \; (\Gamma' \, ; \; c_x : Case \llbracket \Sigma; \; \Gamma \vdash A \rrbracket) \end{split}$$

## 4 Semantics

Preliminary definitions and constructions

#### 4.1 Presheaves

Redo using the presentation of Presheaves as "Predicators"

Let C be a small category. A **presheaf** on C is a functor  $F: C^{op} \to Set$ . Psh(C) denotes the functor category where objects are presheaves on C. This category will be used to denote value types. We will want a doubly cartesian closed structure on this category.

#### 4.1.1 Terminal Object

The terminal object  $\top$  is a functor  $\top$ :  $C^{op} \to Set$ . Have  $\top_0(X) := \{*\}$  where  $\top$  maps all objects of  $C^{op}$  to a singleton set. Have  $\top_1(f:X \to Y) : * \to *$  so  $\top$  maps morphisms in  $C^{op}$  to the identity function on the singleton set \*. Say  $F:C^{op} \to Set$  is an object in Psh(C) and consider the natural transformation  $F \Rightarrow \top$ .

$$F(X) \xrightarrow{F(f)} F(Y)$$

$$\downarrow \alpha_X \qquad \qquad \downarrow \alpha_Y .$$

$$\perp (X) \xrightarrow{id_{\{*\}}} \perp (Y)$$

Any natural transformation from F to  $\bot$  is determined by the components, of which there is no choice but the terminal map in Set. Thus, Psh(C) has a terminal object.

#### 4.1.2 Products

Given F, G presheaves on C, construct their product object in  $[C^{op}, Set]$ .

On objects:

$$(F \times_{Psh(C)} G)(X) := F_0(X) \times_{Set} G_0(X)$$

On morphisms: given  $(f: X \to Y)^1$ 

$$(F \times_{Psh(C)} G)(f) : (F_0(X) \times_{Set} G_0(X)) \to (F_0(Y) \times_{Set} G_0(Y))$$
  
 $(F \times_{Psh(C)} G)(f)(Fx, Gy) := (F_1(f)(Fx), G_1(f)(Gy))$ 

Preserves identity (holds pairwise)<sup>2</sup>

$$(F \times_{Psh(C)} G)(id_X) = F_1(id_X), G_1(id_X)$$
$$= id_{F_0(X)}, id_{G_0(X)}$$
$$= id_{(F \times_{Psh(C)} G)(X)}$$

Preserves composition (holds pairwise)

$$\begin{split} (F \times_{Psh(C)} G)(g \circ f) &= F_1(g \circ f), G_1(g \circ f) \\ &= F_1(g) \circ F_1(f), G_1(g) \circ G_1(f) \end{split}$$

 $<sup>\</sup>overline{\begin{tabular}{l} $1$} (f^{op}:Y\to X). \label{eq:condition} Alternatively, we could write something like $\langle F_1(f)\circ\pi_1,G_1(f)\circ\pi_2\rangle$. Being in set, we are abusing notation in the function definition by implicitly abstracting over $(F_0(X)\times_{Set}G_0(X))$ and unpacking/repacking products $^2$ Again I am abusing notation by performing implicit "computation" in Set$ 

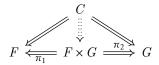

This describes an object  $F \times_{Psh(C)} G \in Psh(C)$ . The projection maps  $\pi_1, \pi_2$  are natural transformations. Consider  $\pi_1 : (F \times G) \Rightarrow F$ .

$$F(X) \times G(X) \xrightarrow{F(f) \times G(f)} F(Y) \times G(Y)$$

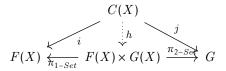

$$\downarrow^{\pi_{1-Set}} \qquad \downarrow^{\pi_{1-Set}}$$

$$F(X) \xrightarrow{F(f)} F(Y)$$

The commuting diagram lives in Set and  $(F \times G)(X) := (F(X), G(X))$ . So the components of  $\pi_1$  are the projections maps of products in Set. From what we know about Set, we know this diagram commutes. What remains is to demonstrate the universal properties for products.

This looks like the usual definition of product except that all the morphism are natural transformations. We can work with functions and sets if consider the underlying components and we fix an arbitrary object  $X \in Ob$  C. We know this commutes because Set has products.

### 4.1.3 Exponentials

To construct the exponential object for two presheaves F, G, we first need to describe the Yoneda embedding.

#### 4.1.4 Yonedda Embedding

The Yonedda Embedding is a functor  $\& : C \to Psh(C)$  which maps an object in C to its contravariant hom functor.

$$\sharp_0(X) := Hom(\_, X)$$

Where Any Y is mapped to the set of maps from Y to X.

$$Hom(\_,X)_1(f:B\to A):Hom(A,X)\to Hom(B,X)$$
  
 $Hom(\_,X)_1(f):=\_\circ f$ 

And the action on morphisms  $f^{op}: A \to B$  is precomposition.

$$Hom(\_, X)(id_A)(g : A \to X) = g \circ id_A$$
  
=  $q$ 

When written pointfree,  $Hom(\_, X)(id) = id_{Hom(A,X)}$ . Finally, given  $f: B \to A$ ,  $g: C \to B$ 

$$Hom(\_,X)(g \circ^{op} f) : Hom(A,X) \to Hom(C,X)$$
  
 $Hom(\_,X)(g \circ^{op} f)(h) = h \circ (f \circ g)$   
 $= (h \circ f) \circ g$   
 $= (Hom(\_,X)(g) \circ Hom(\_,X)(f))(h)$ 

 $\sharp_1$  maps morphisms in C to a natural transformation between hom functors.

$$\sharp_1(f:X\to Y):Hom(\_,X)\Rightarrow Hom(\_,Y)$$

With components

$$\eta(Z): Hom(Z, X) \to Hom(Z, Y)$$

$$\eta(Z) = f \circ _{-}$$

such that for any morphism  $g: W \to V$  in C,

$$Hom(V,X) \xrightarrow{Hom(g) = _{\circ}g} Hom(W,X)$$

$$\downarrow \eta = f \circ _{-} \qquad \qquad \downarrow \eta = f \circ _{-}$$

$$Hom(V,Y) \xrightarrow{Hom(g) = _{-}\circ g} Hom(W,Y)$$

Pointwise, the naturality condition is  $(f \circ h) \circ g = f \circ (h \circ g)$  which holds by associativity of functions in Set. What remains is the preservation of identity and composition.

$$\sharp_1(id_X): Hom(\_, X) \Rightarrow Hom(\_, X)$$

Where, for a morphism  $g: W \to V$ ,

$$\begin{array}{ccc} Hom(V,X) & \xrightarrow{Hom(g) = \_\circ g} & Hom(W,X) \\ \eta = id_X \circ \_ & & & \downarrow \eta = id_X \circ \_ \\ Hom(V,X) & \xrightarrow{Hom(g) = \_\circ g} & Hom(W,X) \end{array}$$

The identity natural transformation where components are the identity function. Both commuting squares boil down to the equation  $_{-} \circ g = _{-} \circ g$ .

$$\begin{array}{ccc} Hom(V,X) & \xrightarrow{Hom(g) = \_\circ g} & Hom(W,X) \\ \downarrow id & & & \downarrow id \\ Hom(V,X) & \xrightarrow{Hom(g) = \_\circ g} & Hom(W,X) \end{array}$$

For morphisms  $f: A \to B$ ,  $g: B \to C$ ,

$$\sharp_1(g \circ f) = \sharp_1(g) \circ \sharp_1(f)$$

$$Iom(V,A) \longrightarrow Hom(h) = \_\circ h \longrightarrow Hom(h) = \_\circ h$$

 $W \xrightarrow{h} V$ 

$$\begin{array}{ccc} Hom(V,A) & \xrightarrow{\quad Hom(h)=\_\circ h \quad} Hom(W,A) \\ & & \downarrow (f\circ g)\circ\_ & & \downarrow (f\circ g)\circ\_ \\ Hom(V,C) & \xrightarrow{\quad Hom(h)=\_\circ h \quad} Hom(W,C) \end{array}$$

$$\begin{array}{cccc} Hom(V,A) & & \stackrel{-\circ h}{\longrightarrow} & Hom(W,A) \\ & & \downarrow^{f\circ\_} & & \downarrow^{f\circ\_} \\ Hom(V,B) & & \stackrel{-\circ h}{\longrightarrow} & Hom(W,B) \\ & \downarrow^{g\circ\_} & & \downarrow^{g\circ\_} \\ Hom(V,C) & & \stackrel{-\circ h}{\longrightarrow} & Hom(W,C) \end{array}$$

The components of each natural transformations are equal.

## 4.1.5 Exponential Object

Given presheaves F, G, the exponential object  $G^F$  is also a presheaf. For an object X of C, we get a set of natural transformations.

$$G_0^F(X) := Hom_{[C^{op}, Set]}( \mathfrak{L}_0(X) \times_{psh} F, G)$$

For a morphism  $f: X \to Y$  of C, we have a function between sets of natural transformations

$$G_1^F(f): Hom_{[C^{op}, Set]}(\mathfrak{L}_0(Y) \times_{psh} F, G) \to Hom_{[C^{op}, Set]}(\mathfrak{L}_0(X) \times_{psh} F, G)$$

Say we are given  $nt: Hom_{[C^{op}, Set]}(\mathfrak{L}_0(Y) \times_{nsh} F, G)$  which has components

$$\alpha: (Z: ObC) \to (Hom(Z, Y), F(Z)) \to G(Z)$$

We map nt to a natural transformation in  $Hom_{[C^{op},Set]}(\ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ )$ , where the components are defined to be:

$$\eta: (Z: ObC) \to (Hom(Z, X), F(Z)) \to G(Z)$$
  
 $\eta(Z)(q: Z \to X, fz: F(Z)) := \alpha(Z)(f \circ q, fz)$ 

Given  $g: W \to V$ , a morphism in C, the naturality square is of the form:<sup>3</sup>

$$F_1(g): F(V) \to F(W)$$
  $G_1(g): G(V) \to G(W)$ 

From our original natural transformation nt, we have the naturality square:

## 4.2 Day Convolution

The Day convolution is used to model our separating connectives  $\_*\_$  and  $\_*\_$ . First, we define the category of **Worlds** and a partial monoidal structure on **Worlds**. Let N be a finite set. Take the objects of **Worlds** to be subsets of N and the morphisms to be set inclusion. Define separation on the subsets of N as:

$$X * Y := \begin{cases} X \cup Y & X \cap Y = \emptyset \\ undefined & otherwise \end{cases}$$

This ensures that X \* Y is only defined when X and Y are disjoint subsets of N.  $(N, \emptyset, *)$  is a partial commutative monoid. When both sides of the equations are defined, we get the usual commutative monoid structure on  $(N, \emptyset, \cup)$ .

To "lift" this to a bifunctor,  $\_*$  is the action on objects.(but the operation is only partial... make N a pointed set?). Given (X\*Y),  $f: X \subseteq X'$ , and  $g: Y \subseteq Y'$ , produce (X'\*Y') not target may not exist.. something seems to be missing?

The Day convolution take the monoidal structure on  $\widehat{World}$  to a monoidal structure on  $\widehat{World}$ .

$$(A*B)X = \int^{Y,Z} \ A(Y) \times B(Z) \times World^{op}[X,Y*Z]$$

The concrete interpretation for this model is

$$(A * B)X = \{ [(Y, Z, a \in A(Y), b \in B(Z))] \mid Y * Z \text{ is defined and } Y * Z \subseteq X \}$$

<sup>&</sup>lt;sup>3</sup>note the type of  $F_1$  and  $G_1$  since the source category is opposite

where  $[\cdot]$  denotes an equivalence class.  $(Y,Z,a\in A(Y),b\in B(Z))$  and  $(Y',Z',a'\in A(Y'),b'\in B(Z'))$  are equivalent if they have the same parent in the order determined by

$$\begin{split} &(Y,Z,a\in A(Y),b\in B(Z))\leq (\,Y',Z',a'\in A(\,Y'),b'\in B(Z'))\\ &\text{if}\\ &f:\,Y\subseteq Y',g:Z\subseteq Z',a'=A(f)a,b'=B(g)b \end{split}$$

And for the "magic wand"
